# SCANWORKS® IJTAG DEVELOPMENT

IJTAG for Chip or Board Design Debug and Non-intrusive Board Test benefits both design and test.

OVERVIEW

ScanWorks® IJTAG Development (IJTAG-DL) software makes it easy to develop IJTAG-based embedded instrument tests. The software supports both standard data formats defined as part of the IEEE 1687-2014 IJTAG standard; Procedural Description Language (PDL) and Instrument Connectivity Language (ICL). Once imported into the IJTAG-DL, an easy drop and drag user interface is available to select operations to build your IJTAG test. The IJTAG tests developed during prototype debug or new product introduction can easily be re-used during the entire product life-span.
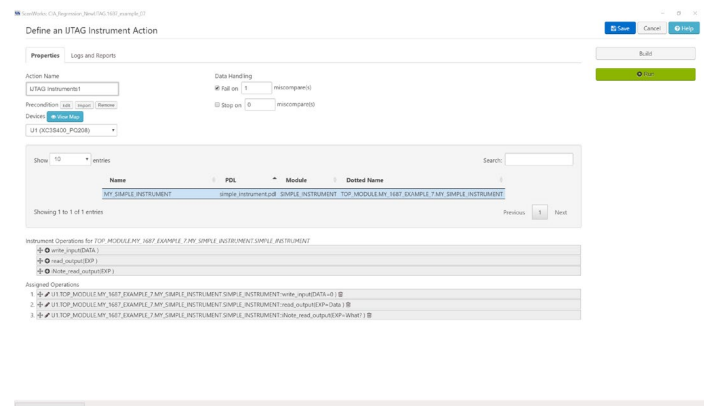

VECTOR AND PROGRAM CREATION

Test vector creation begins with the instrument creation during the design cycle. The instrument operations are described in PDL models, written by the instrument designer or test developer. Once the instruments PDL models are created, they can be archived and easily re-used in the automated model-based environment the ScanWorks Platform provides.

When the instruments are placed into an IJTAG design, an ICL file will be generated that describes the scan path access to the embedded instrument. The IJTAG development software then uses the instrument's corresponding PDL file(s) to operate the instrument. Multiple instrument operations can be organized in a single IJTAG action. In fact, multiple instruments can be operated at the same time providing excellent throughput and test times.

Driving Embedded Instrumentation
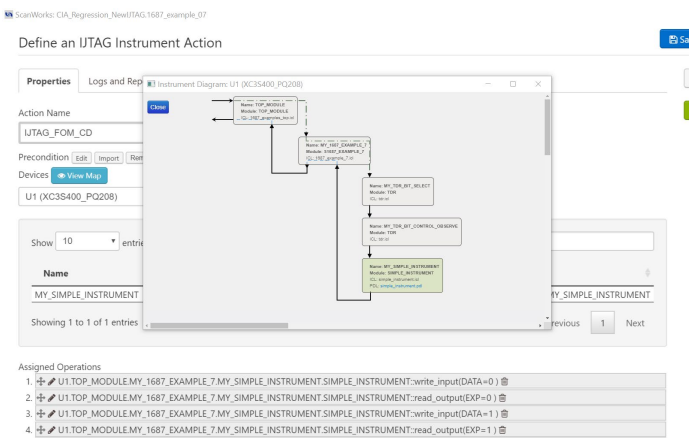

DIAGNOSTICS

The use of PDL and ICL provides far more flexibility and better resources for diagnosing the IJTAG tests than what can be achieved by running the tests from standard SVF (serial vector files). Advanced diagnostics can be generated in PDL for each specific instrument. The limitation on the resolution of diagnostic granularity is only down to the actual instrument's intrinsic hardware capabilities.

DEBUGGING IJTAG TEST PROGRAMS

The ScanWorks IJTAG Development software can be used to apply the IJTAG test program to validate instrument execution, data collection and diagnostic resolution in preparation for manufacturing deployment. Once the functionality of the instruments operations and actions are validated, the project may be exported to manufacturing through the normal ScanWorks platform process.

IJTAG TEST HARDWARE

ScanWorks come with a wide range of controllers on buses like PCI, PCIe, Ethernet, USB, PXI. The controllers typically support voltage levels from 0.8 to 3.3V (5V), TCK speed up to 50 MHz. All active controllers are Windows 32/64-bit compatible, and come with a number of digital IO channels for custom applications.

SCANWORKS PLATFORM FOR EMBEDDED INSTRUMENTS

ScanWorks Platform for Embedded Instruments is a seamless software environment to access, run and collect data from any instrument in your chips, circuit boards or systems. The ScanWorks Platform includes products for Boundary-Scan Test (BST), FPGA-Fast Programming (FFP) and IJTAG test.
